Roundabouts are a great safety solution for rural intersections

Roundabouts have been used in New Zealand for many decades, mainly in urban environments. More recently, a number of rural roundabouts have been installed at high speed main road intersections in Waikato and Auckland to address serious crash concerns.

Recent analysis looking at the results of nine sites confirms just how effective they are.

This case study includes the analysis of these nine sites:

<table>

How much do rural roundabouts usually cost?
The Standard Safety Intervention Toolkit includes a cost range of $2–5 million. Costs are heavily dependent on size, land, services and traffic management during construction.

How effective are rural roundabouts?
- Austroads found roundabouts were effective in reducing fatal crashes by 63–100% and severe crashes by 37–90%.
- The Waka Kotahi NZ Transport Agency Standard Safety Intervention Toolkit says rural roundabouts have an assumed death and serious injury reduction of 60%.

Our recent New Zealand analysis of nine sites

Across the nine sites:
- In the five years before installation, there were 46 reported injury crashes.
- Since installation, there have been nine reported injury crashes, with no fatal crashes and three serious crashes.

A statistical analysis undertaken by Waka Kotahi data analysis team has compared the crash rates on a monthly basis across all sites individually and combined, noting that post-construction periods vary but are typically less than five years and so are not directly comparable to the pre-construction period.

Our analysis found:
- The fatal and serious crashes, and deaths and serious injuries equivalents (the estimated number of deaths and injuries), have reduced by 75%. From an average of 0.04 per month (0.5 per year) to 0.01 per month.
- Total crashes (injury and non-injury) reduced by 50%. From a monthly average of 0.26 per month to 0.13.

A review of crashes after installation also found:
- Loss of control was the most common type, followed by changing lanes.
- There were two motorcycle injury crashes, compared to 16 motorcycle injury crashes before installation.
- There have been no reported cyclist or pedestrian crashes, however, numbers of pedestrians and cyclists would be extremely low at rural sites.

Total crashes per month - pre- and post-construction

</tr>
</tbody>
</table>

*Total crashes includes all reported injury and non-injury crashes. All combined results are statistically significant. Please note that pre- and post-construction time periods are not the same. This is a simple before and after analysis without control site comparison.
Key tips for practitioners

- Roundabouts are a great Safe System intersection solution, with significant reductions in deaths and serious injuries, even in remote high-speed locations. Simplified decision making reduces errors and speeds, and low impact angles reduce injury severity when mistakes are made.
- The Waka Kotahi Standard Safety Intervention Toolkit also rates rural roundabouts as a ‘Safe System transformation’ treatment philosophy. Roundabouts are included as a ‘primary Safe System treatment’ as they significantly reduce the risk of someone being killed or seriously injured.
- The key to a safe outcome is managing entry speed. Single lane roundabouts should be used wherever possible, as this minimises the risk of crashes when changing lanes and is safer for vulnerable road users. Large roundabouts can be expensive, and exploring the opportunity for low-cost compact roundabouts, with innovative speed management techniques, offer potential opportunities.
- We can take more innovative approaches to rural roundabouts to gain the benefits at intersections. Recently Victoria Australia has been trialling the installation of lower cost compact rural roundabouts, with raised platforms on the approaches to help manage traffic spreads.
- Roundabouts deliver near Safe System outcomes for vehicle occupants and should be the starting point for any road project considerations. This doesn’t mean roundabouts must be used in all circumstances – context is important. However they should at least be considered first due to their superior harm reduction potential over other intersection types.

Thank you to Colin Brodie for leading the analysis of this case study.
